Perioperative Transfusion Stewardship

Anesthesiology Performance Improvement and Reporting Exchange (ASPIRE)
Objectives

• Discuss risks and outcomes associated with transfusion
• Describe ASPIRE transfusion measures
• Provide general recommendations based on American Society of Anesthesiologists (ASA) Transfusion Guidelines (2015)
• Review best practices when transfusion cannot be avoided
• Summarize ASPIRE recommendations based on literature presented
Risks Associated with Transfusion

- Acute kidney injury
- Anaphylaxis
- Hemolytic transfusion reaction
- Transfusion-associated sepsis
- Transfusion-related acute lung injury (TRALI)
- Transfusion-associated circulatory overload
- Transfusion-associated graft-versus-host disease

## Approximate Risk Per-Unit Transfusion of RBCs

### Table 1. Approximate Risk Per-Unit Transfusion of Red Blood Cells (RBCs)

<table>
<thead>

Adj = adjusted; CI = confidence interval; CNS = central nervous system; OR = odds ratio; PS method = propensity score method; Txf = transfusion; Unadj = unadjusted.

Glance et al. Anesthesiology. 2011;114(2):283-292. PMID: 21239971
Outcomes Associated with Perioperative Blood Transfusion

• Transfusion based on a liberal trigger is associated with worse patient outcomes and increased institutional cost compared with a restrictive trigger.¹

• Patients who received one or two units of rbcs had a 29% increased odds of death and a 40-90% increased odds of pulmonary, sepsis, wound, and thromboembolism complications.²

• 30-day mortality rate for patients who were transfused was 6.44% versus 4.26% for patients who were not transfused.²

• Restricting blood transfusions using a restrictive trigger of ≤ 7 g/dL results in a significant reduction in total mortality, acute coronary syndrome, pulmonary edema, re-bleeding, and bacterial infection compared with more liberal transfusion strategy.³

¹Ejaz et al. JAMA surgery. 2015;150(7):625-630. PMID: 25946411
²Glance et al. Anesthesiology. 2011;114(2):283-292. PMID: 21239971
Financial Impact: Total cost of a single unit of PRBCs

• Actual institutional acquisition costs approximately $220 per unit

• Estimated mean activity-based cost of transfusion: $760 per unit ($522-$1183) takes into account acquiring, delivering, administering, and monitoring each transfusion

Ejaz et al. JAMA surgery. 2015;150(7):625-630. PMID: 25946411
Transfusion Recommendations & Guidelines
ASA Practice Guidelines for Perioperative Blood Management

- Preoperative Evaluation
- Preadmission Patient Preparation
- Pre-procedure Preparation
- Intraoperative and Postoperative Management of Blood Loss

Anesthesiology. 2015;122(2):241-275. PMID: 25545654
Preoperative Evaluation

Perform several days to weeks in advance, if possible.

- Review Previous Medical Records & conduct a Patient/Family Interview
  - Previous blood transfusion?
  - History of drug-induced coagulopathy?
  - Presence of congenital coagulopathy?
  - Risk factors for organ ischemia?
  - History of thrombotic events?

- Review existing lab results (hemoglobin, hematocrit, coagulation profiles)

- Order additional lab tests based on patient’s condition (anemia, coagulopathy)

- Conduct physical exam (ecchymosis, petechiae, pallor)

Prior to surgery, inform patient of potential risks vs. benefit of blood transfusion and identify patient preferences.
Preadmission Patient Prep Recommendations

• Prevention or reduction of perioperative anemia
  – Administration of erythropoietin can reduce need for RBC transfusions in patients with perioperative hemoglobin 10-13 g/dL who are at high risk for perioperative blood loss from elective, non-cardiac, non-vascular surgery.
  – Iron (IV infusion or daily oral administration)

• Discontinue anticoagulants/antithrombotic agents
  (Consider patient condition and risk factors)
  – Warfarin: 5 days before surgery; check PT/INR day of surgery.
  – Clopidogrel or other thienopyridines: Discontinue 5 days before surgery.
  – Aspirin: Discontinue 7-10 days before surgery (but not all do)

• Preadmission autologous blood donation (PAD)
  – Though autologous blood donation can reduce the use of allogenic blood transfusion by 40-52%, PAD is not found to be cost-effective as compared to other blood sparing strategies.\(^3\)

Pre-procedure Preparation Recommendations

Adopt Blood Management Protocols
- Multimodal protocol or algorithm
- Restrictive vs liberal transfusion protocol
- Non-transfusion protocol (bloodless surgery)
- Massive transfusion protocol
- Maximum surgical blood ordering schedule for elective procedures

Reversal of anticoagulants
- Vitamin K
- Prothrombin Complex Concentrates

Antifibrinolytics for prophylaxis of excessive blood loss
- Aminocaproic acid
- Tranexamic acid

Acute Normovolemic Hemodilution: Consider for cardiac and ortho procedures

1. Anesthesiology. 2015;122(2):241-275. PMID: 25545654
Intraoperative and Postoperative Management of Blood Loss

• Allogenic Red Blood Cell Transfusion
  – Age of Stored Blood (controversial - no firm conclusions)
  – Leukocyte reduction: reduces complications associated with transfusion

• Reinfusion of recovered red blood cell transfusion (cell saver administration supported)

• Intraoperative and postoperative patient monitoring
  – Monitor blood loss
  – Perfusion of vital organs
  – Anemia
  – Coagulopathy

• Treatment of excessive bleeding

Anesthesiology. 2015;122(2):241-275. PMID: 25545654
Treatment of Excessive Bleeding

- ASA Practice Guidelines for Perioperative Blood Management
  - Transfusion of Platelets: Obtain platelet count before transfusion
  - Transfusion of FFP: Obtain coagulation tests (INR or PT and aPTT) before transfusing FFP
  - Transfusion of Cryoprecipitate: Assess fibrinogen levels before giving cryo
  - Pharmacologic Treatment of bleeding
    - DDAVP (0.3u/kg)
    - Antifibrinolytics (tranexamic acid, aminocaproic acid)
    - Topical hemostatics (fibrin glue, thrombin gel)
    - PCCs and rVIIa (careful if vascular anastomoses)
    - Treatments for hypofibrinogenemia (cryoprecipitate, rec fibrinogen)
Clinical Practice Guidelines from AABB (American Association of Blood Banks)

• **Recommendation #1**: Transfusion is not indicated until hemoglobin level is 7 g/dL for hospitalized adult patients who are hemodynamically stable, including critically ill patients.*

• **Recommendation #2**: Transfusion threshold of 7-8 g/dL is indicated for patients undergoing orthopedic or cardiac surgery, and those with preexisting cardiovascular disease.*

• **Recommendation #3**: Patients, including neonates, should receive RBC units selected at any point within their licensed dating period rather than limiting patients to transfusion of only fresh (≤10 days) RBC units.

*Recommendations do not apply to patients with Acute Coronary Syndrome, severe thrombocytopenia, and chronic transfusion-dependent anemia.

Mueller et al. Jama. 2019; 321(10), 983-997. PMID: 30860564
Transfusion Triggers: Literature Review

Red Cross Transfusion Guidelines:

- RBCs should be administered based on signs and symptoms, Hgb level, and hematologic results
- In the absence of acute hemorrhage, RBCs should be administered as single units, followed by appropriate evaluation to justify additional units.
- Complete administration of a single unit within 4 hours

Post-transfusion Considerations:

- In a non-bleeding, non-hemolyzing adult, the hemoglobin should equilibrate within 15 minutes after transfusion of RBCs.
- It is estimated that one RBC unit should increase Hgb by approximately 1g/dL or Hct by 3%.

Transfusion Triggers: Literature Review

National Institute for Health and Care Excellence (NICE) Guidelines:

• Use Restrictive RBC Hgb Thresholds (7 g/dL) for patients who need RBC transfusions but do not have:
  - Major hemorrhage
  - Acute Coronary Syndrome
  - A need for regular blood transfusions for chronic anemia

• Post-transfusion Hgb target (goal) for restrictive therapy: 7-9 g/dL

• In patients with acute coronary syndrome, consider transfusion threshold of Hgb: 8 g/dL and target of 8-10 g/dL

• Set individual thresholds and targets for patients with chronic anemia

• Consider single unit red blood cell transfusions for adults who do not have active bleeding

• After each single unit of RBC transfusion, clinically reassess and check Hgb levels before administering additional units.

Mueller et al. Jama. 2019; 321(10), 983-997. PMID: 30860564
Transfusion Trigger Considerations in Cardiac Surgery

Transfusion Trigger Recommendations

Cardiac Surgery
Percentage of Cardiac Cases Receiving a Transfusion per ASPIRE Measure Criteria

Transfusions Included

Transfusions Excluded
Conflicting definitions of restrictive transfusion presented in the literature:

- In one review, there was no significant increase in rates of myocardial infarction, stroke, acute renal failure, or mortality using restrictive transfusion thresholds (Hgb: 7-9 g/dL) in patients undergoing cardiovascular surgery.¹

- Low Hgb (<7) values are associated with increased operative mortality, increased likelihood of prolonged intensive care stay and greater likelihood of postoperative hospitalization of 9 or more days.²

- Restrictive transfusion thresholds (Hgb: 7-8 g/dL) are associated with higher rates of acute coronary syndrome in anemic patients compared with more liberal transfusion thresholds (9-10 g/dL).³

¹Curley et al. Critical care medicine. 2014;42(12):2611-2624. PMID: 25167086
³Docherty et al. BMJ (Clinical research ed). 2016;352:i1351. PMID: 27026510
Liberal vs. Restrictive Transfusion Strategy in Cardiac Patients

- 110 Patients
- Restrictive: <8 g/dL
- Liberal: <10 g/dL
- Restrictive transfusion strategy resulted in increased rate of death (18.5% vs. 12.7%).

P value: 0.032

Transfusion Recommendations: Cardiac Surgery

Cell Saver

- Transfusion through cell saver is safe and results in a significant reduction in homologous transfusion. Pts who receive intraoperative cell saver transfusion (ICT) also have decreased mediastinal drainage 12 hours postoperatively.¹
- Hgb levels fell significantly in patients on day 1 post-op.²
- Major concerns regarding the use of cell saver include:
  - Possible increase in the systemic inflammatory response³,⁴
  - Coagulopathy postoperatively⁵
  - An increased risk of fat and air emboli⁶
  - Organ Failure⁷,⁸

⁴Amand et al. Perfusion. 2002;17(2):117-123. PMID: 11958302
⁵Daane et al. Perfusion. 2003;18(2):115-121. PMID: 12868789
Mazer et al (2017) NEJM

RCT of 5743 mod-high risk heart surgery patients: restrictive (7.5 g/dl) vs liberal (9.5 g/dl)

Good group separation

No difference death

Slightly longer ICU LOS in restrictive group

No difference AKI rates, but less blood given to restrictive group
Optimizing Perfusion: Anemia Tolerance & Transfusion

- Transfusion Trigger during CPB was 22%
- $\% \Delta Cr =$ The peak postoperative change in serum creatinine level relative to pre-CPB values.
- Acute renal injury and failure (ARF) after cardiopulmonary bypass (CPB) has been linked to low on-pump hematocrit.

Increasing rates of AKI are seen as the HCT dips below 20-21% during CPB. Occurs whether the patient is transfused or not. Transfusion itself also increases the risk of AKI.

Anemia and Hypotension: Co-Occurrence during CPB

• The likelihood of acute kidney injury with CPB-anemia does not change with different blood pressure values as measured at the time when the lowest CPB hematocrit occurred.

Hypotension, Anemia Tolerance during CPB and Postoperative Acute Kidney Injury

Sickeler et al Ann Thor Surg 2014; 97; 865-71
Hemodilution and Transfusion

Minimizing hemodilution and avoiding unnecessary transfusion is best practice.

STS Guideline Recommendations

- Multidisciplinary and multi modality:
  - Mini-circuits
  - Microplegia
  - Modified ultrafiltration
  - Blood salvage

Ann Thorac Surg 2011;91:944-82
Patients with both anemia and hypotension during CPB did not differ in rates of AKI with those of anemia alone but did differ from patients with hypotension alone and patients with neither anemia or hypotension.
Massive Transfusion Protocols

Develop with multi-disciplinary committee that includes:
- Transfusion service/blood bank
- Emergency department
- Anesthesia
- Trauma Service

Massive Transfusion Protocol should address:
- Triggers for initiating massive transfusion in trauma
- Resuscitation in the trauma bay
  - MTP Product Availability
  - MTP Product Delivery
  - MTP Blood Product Transfusion
- Continuing MTP in OR, Angiography suite, ICU
- Transfusion service processes for delivery of blood products
- Transfusion targets
- Use of adjuncts for massive transfusion patients
- Termination of MTP
- Performance Improvement Monitoring

For more information: American College of Surgeons
American College of Obstetrics and Gynecology (ACOG) released the Safe Motherhood Initiative in 2013.

- Blood transfusion or cross-matching should not be used as a negative quality marker and is warranted for certain obstetric events.
- In cases of severe obstetric hemorrhage, ≥4 units of blood products may be necessary to save the life of a maternity patient.
- Hospitals are encouraged to coordinate efforts with their laboratories, blood banks, and quality improvement departments to determine the appropriateness of transfusion and quantity of blood products necessary for these patients.

For more information and resources, please visit the ACOG website: [ACOG Obstetric Hemorrhage Bundle](#)
Obstetric Hemorrhage Protocol Pocket Card

ASPIRE (MPOG) Recommendations

• Use the literature to develop evidence-based institution transfusion protocols and guidelines

• Restrictive transfusion protocols should be considered for asymptomatic patients

• There is rarely an indication to transfuse any patient with a Hgb >10g/dL

• Decision to transfuse should be based on objective assessment of the patient, including Hgb/Hct

• In the absence of acute hemorrhage, transfuse one unit at a time

• Reassess post-transfusion to determine if additional units are required
Thank you
